

PhD defense – *September 17, 2021*

Near infrared spectroscopy applied to solid organic waste: how to avoid water effects?

Alexandre MALLET

*Under the direction of Jean-Philippe STEYER and Jean-Michel ROGER
Co-supervised by Eric LATRILLE, Ryad BENDOULA and Cyrille CHARNIER*

0.1 Agenda

Summary of contents

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

3.4 – Local modeling

4 – Conclusions and perspectives

1. Introduction, context, scientific objectives

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

3.4 – Local modeling

4 – Conclusions and perspectives

1.1

Introduction, context, scientific objectives

The anaerobic co-digestion process

Inputs

Biowaste

Crop residues

Animal manure

Sludge from sewage treatment

Urban and industrial effluents

New biomass

Anaerobic Digestion

Outputs

Biogas (CH₄)

- Combined Heat Power (CHP)
- Gas grid injection
- Vehicle fuel

Digestate

Fertilizer

- Highly diverse biochemical and physical properties
- Daily fluctuations of quality/quantity

➤ How to optimize the feeding recipe?

➤ Requires fast and reliable substrate characterization tools

1.1

Introduction, context, scientific objectives

Substrate characterization: the biochemical methane potential (BMP)¹

Organic waste

Anaerobic digestion
30-60 days

Monitoring of gas production

Angelidaki et al., *Water Science Technology*, 2009.

1.1 Introduction, context, scientific objectives

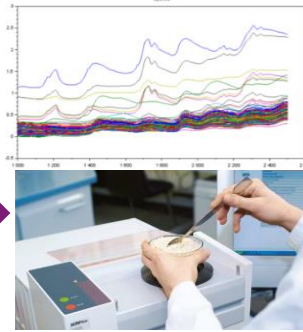

Operational context: a NIRS-based characterization tool (IRSCAN)

Substrates (organic waste)

NIR scan

(reflectance mode
& 1000-2500 nm)

Chemometrics

- **Methane potential (BMP)¹**
- Proteins²
- Lipids²
- Carbohydrates²
- Chemical Oxygen Demand (COD)²
- CH₄ kinetics²

[1] Lesteur et al., *Bioresource Technology*, 2011.

[2] Charnier et al., *Waste Management*, 2016.

Freeze-drying
and grinding

0

4 days

Advantages

- **Fast measurement** (4 days vs. 1-2 months)
- Applicable **on high diversity of waste**
- Accuracy and **reproducibility**
- Possible to optimize feeding strategy

Hurdles

- **Sample preparation is required** to reduce effects of water and particle size :
 - **Time-consuming step** + additional costs
 - **Loss of volatile fraction** during drying
 - **Limits online applications**

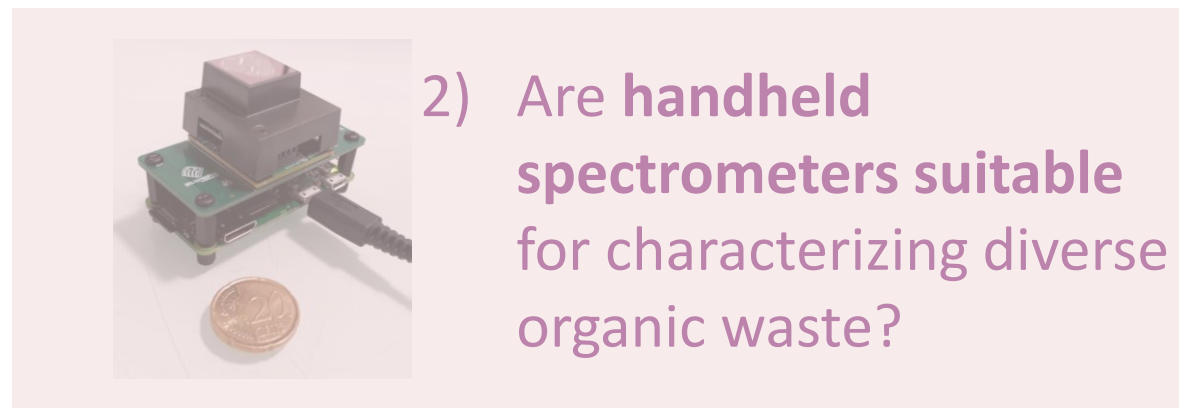

1.1 Introduction, context, scientific objectives

Operational context: online and on-site analysis of substrates

➤ Can we **avoid freeze-drying steps**, and **analyze fresh matter** by NIRS directly?

1) Can **modeling strategies** be found to account for **water effects**?

2) Are **handheld spectrometers** suitable for characterizing diverse organic waste?

➤ **Potential applications:**

➤ Online analysis

➤ On-site analysis

1.2 Introduction, context, scientific objectives

How to build robust models against water effects?

Can the influencing factor be controlled?

Sample preparation
(grinding, drying, dilution, filtering)

Can the measurement method be less influenced by the factor?

Measurement mode
(reflectance/transmittance/interactance, distance/contact, polarization)

Can the model pipeline be less influenced by the factor?

Pre-processing, modeling

1.3 Introduction, context, scientific objectives

Scientific objectives

- 1) To develop a better understanding of the moisture content effects on NIRS applied to a wide range of organic materials

- 2) To find new ways of building models that are robust to moisture content effects

2.

Materials & Methods

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

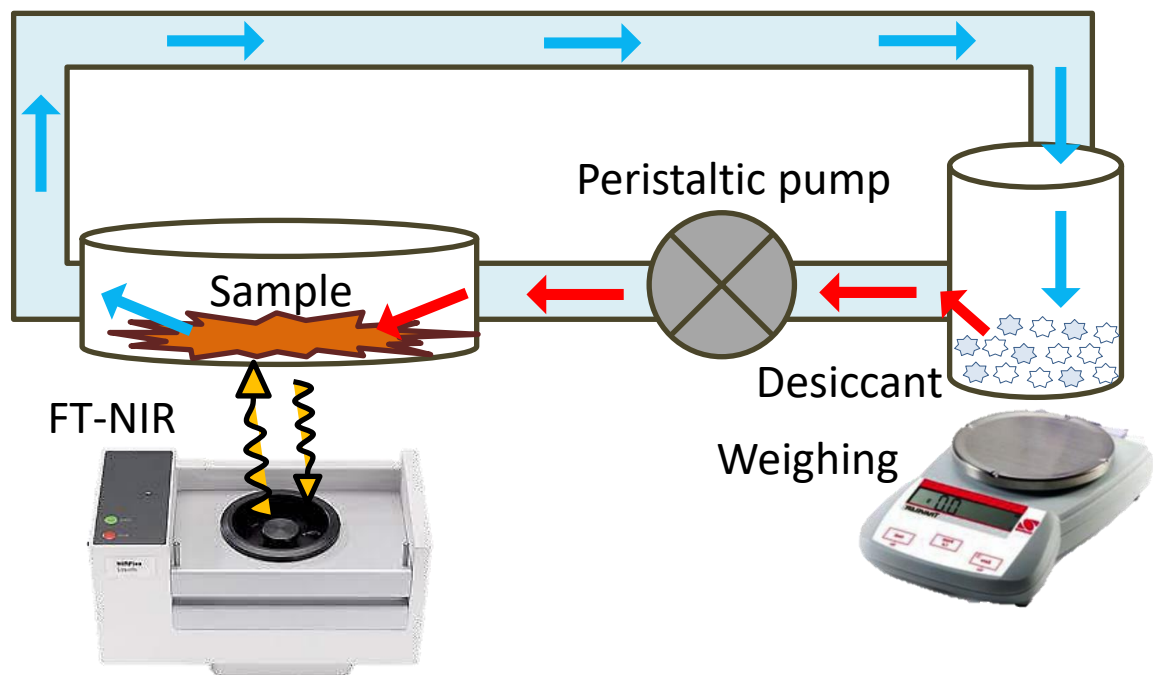

3.4 – Local modeling

4 – Conclusions and perspectives

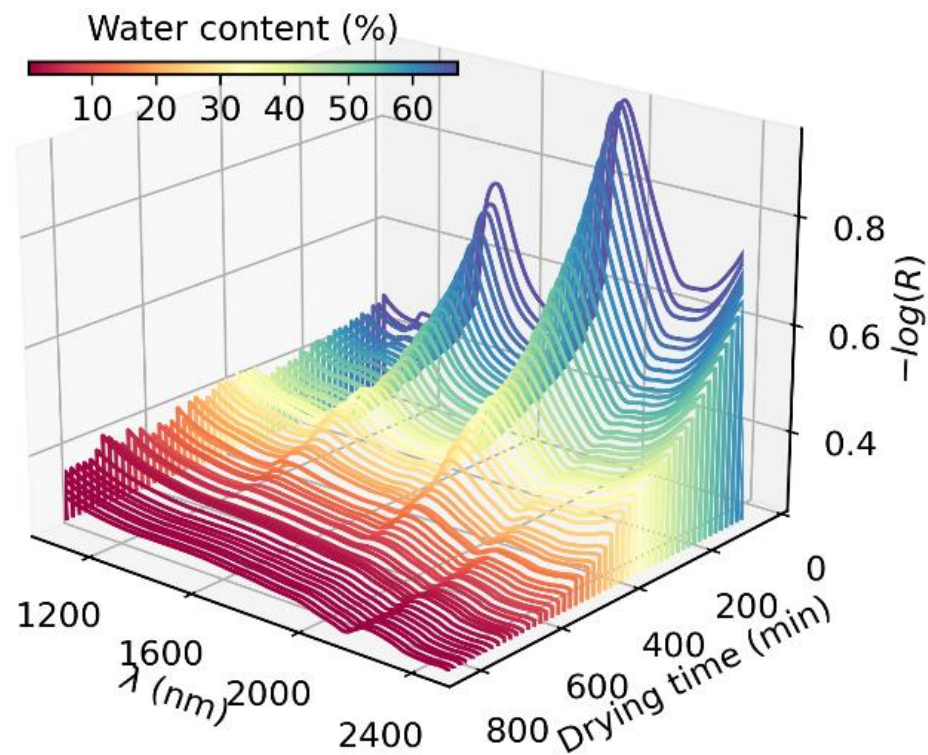

2.1 Materials & Methods

An innovative system to collect spectral variations related to water variations

- Closed circuit air-drying system with NIRS and water content monitoring

- Evolution of NIR spectra with water content %

- 89 substrates, 120 000 spectra, DM% = 1-99%
- Analysis of each substrate with IR-SCAN (freeze-dried/ground spectra + characterization in lipids/proteins/carbohydrates/COD)

2.2 Materials & Methods

Analyzed substrates

➤ A wide range of physical properties and biochemical composition

3.1 Results – Global correction of models

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

3.4 – Local modeling

4 – Conclusions and perspectives

3.1 Global correction of models

Objective, Materials & Methods

➤ Objective:

- Evaluate global correction methods to account for moisture content variations in a calibration model (*i.e.*, a « one global model for all »)
- BMP prediction

➤ Workflow:

3.1 Global correction of models

Objective, Materials & Methods

➤ Methods evaluated:

Feature selection
(*cut water bands*)

Wu et al., Soil Science, 2009.

Scaling, skewing
(GLSW)

Bro et al., Journal of Chemometrics, 2003.
Martens et al., Journal of Chemometrics, 2003.

Orthogonal projections
(*EPO, OSC-EPO*)

Roger et al., Chem. Intel. Lab. Systems, 2003.
Preys et al., Chem. Intel. Lab. Systems, 2008.

Transfer (*PDS*)

Wang et al., Analytical Chemistry, 1991.
Ji et al., Eur. Jour. of Soil Science, 2015.

Model update

Andries et al., Journal of Chemometrics, 2019.

Repeatability file

Tillman et al., Jour. of Near Infrared Spectroscopy, 1998.

Stacking

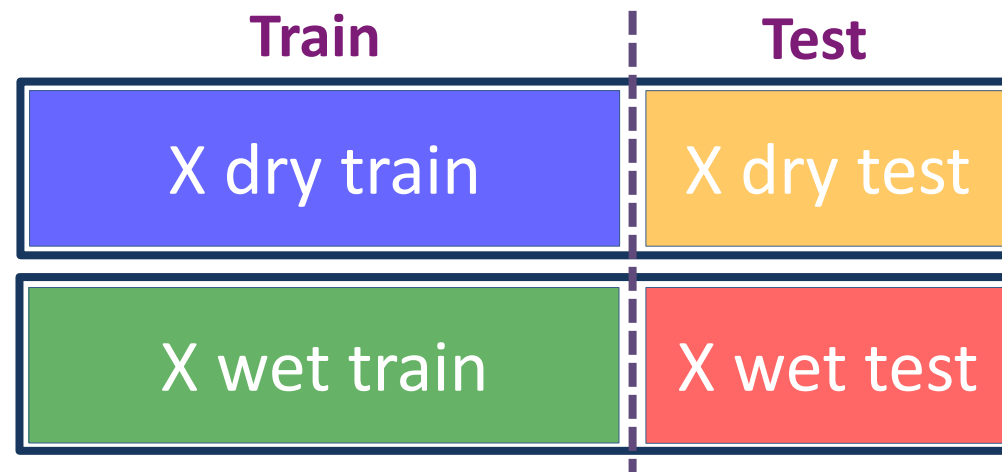

➤ Datasets:

Freeze-dried and
ground samples

= **X dry**

Raw samples analyzed
during drying

= **X wet**

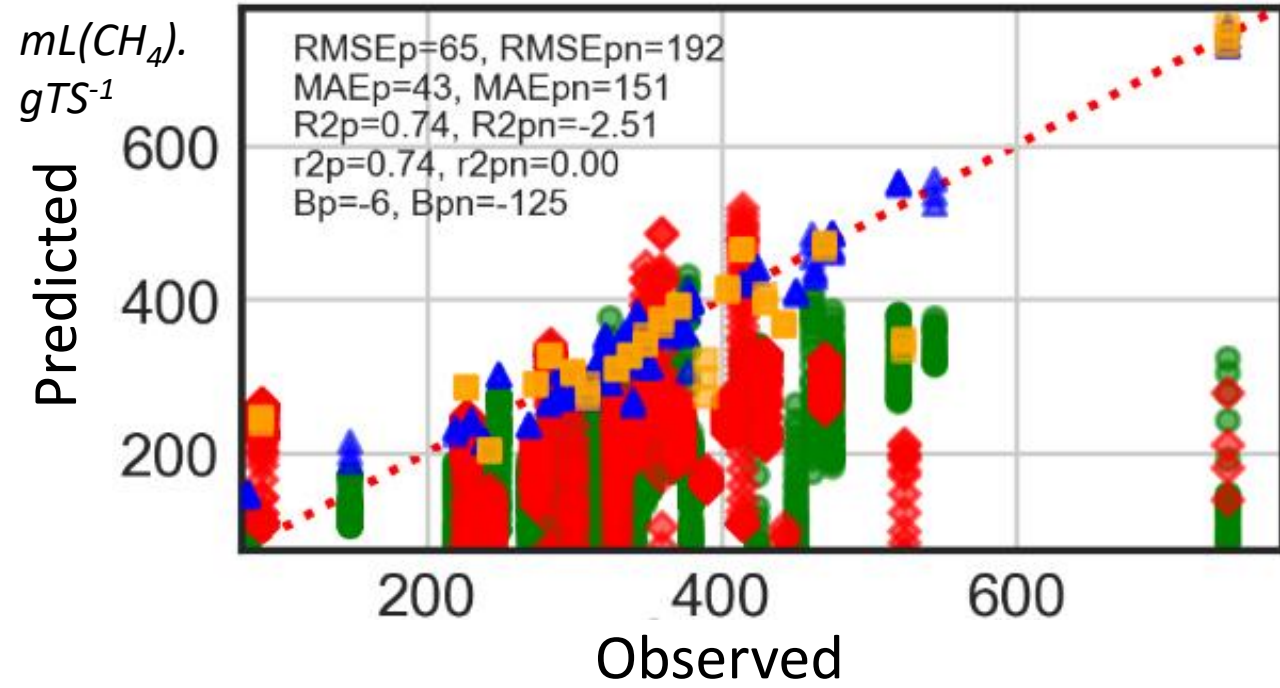

3.1 Global correction of models

Results – model performances

⋯ Identity line
 ▲ X dry train
 ■ X dry test
● X wet train
 ◆ X wet test

Original model (no correction)

With correction (Repeatability File)

3.1 Global correction of models

Results – model performances

Identity line X dry train X dry test
 X wet train X wet test

Original model (no correction)

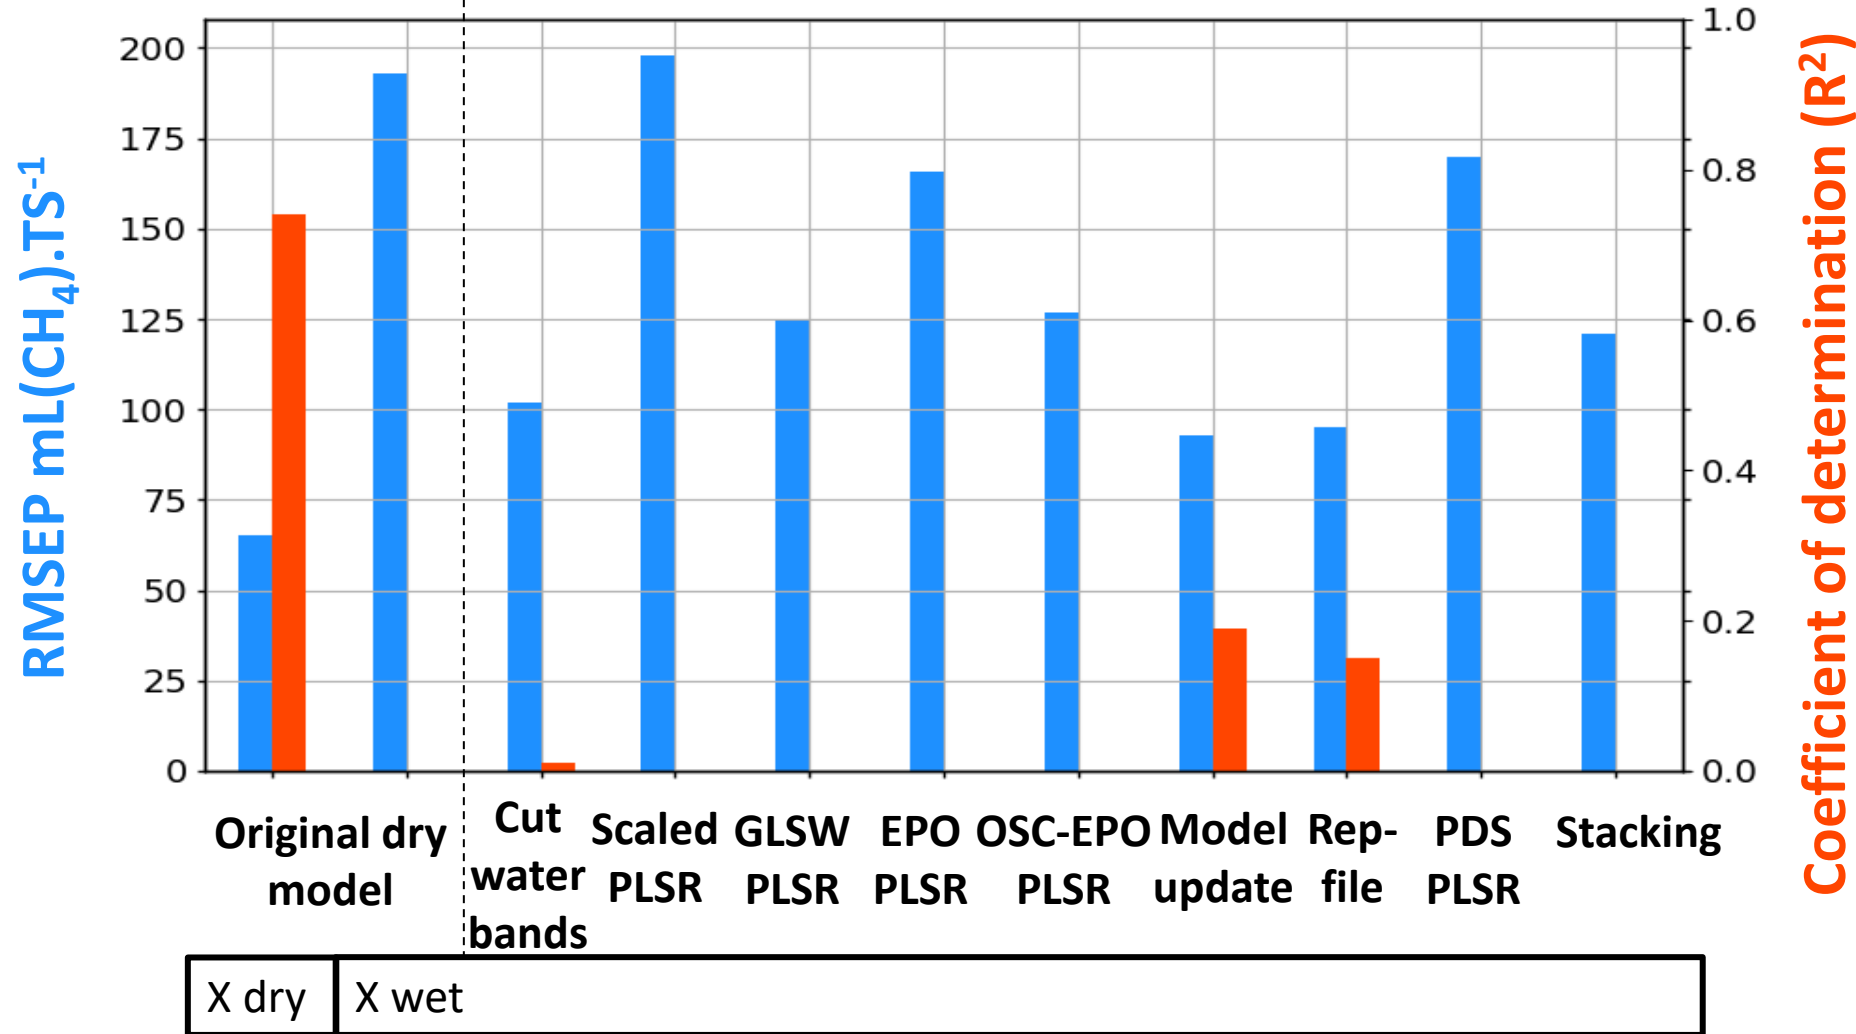

With correction (Repeatability File)

3.1

Global correction of models

Results – model performances (all methods)

➤ None of the global correction methods allowed significant improvements

3.1 Global correction of models

Results – prediction quality differs according to substrates

➤ Prediction error depends on substrate:

➤ Implies:

- i. Different sensitivities to moisture content effects
- ii. Different types of moisture content effects

➤ Conclusion:

➤ A need to better assess moisture content effects according to substrate types

3.2 Results – non-linearity of water effects

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

3.4 – Local modeling

4 – Conclusions and perspectives

3.2 Non-linearity of water effects

Objective, Materials & Methods

- **Objective:**
 - Analyze moisture content effects according to 1) substrate type and 2) moisture content level
 - Using principal components analysis (PCA):

3.2

Non-linearity of water effects

Water affects physical properties (*ie.*, scattering)

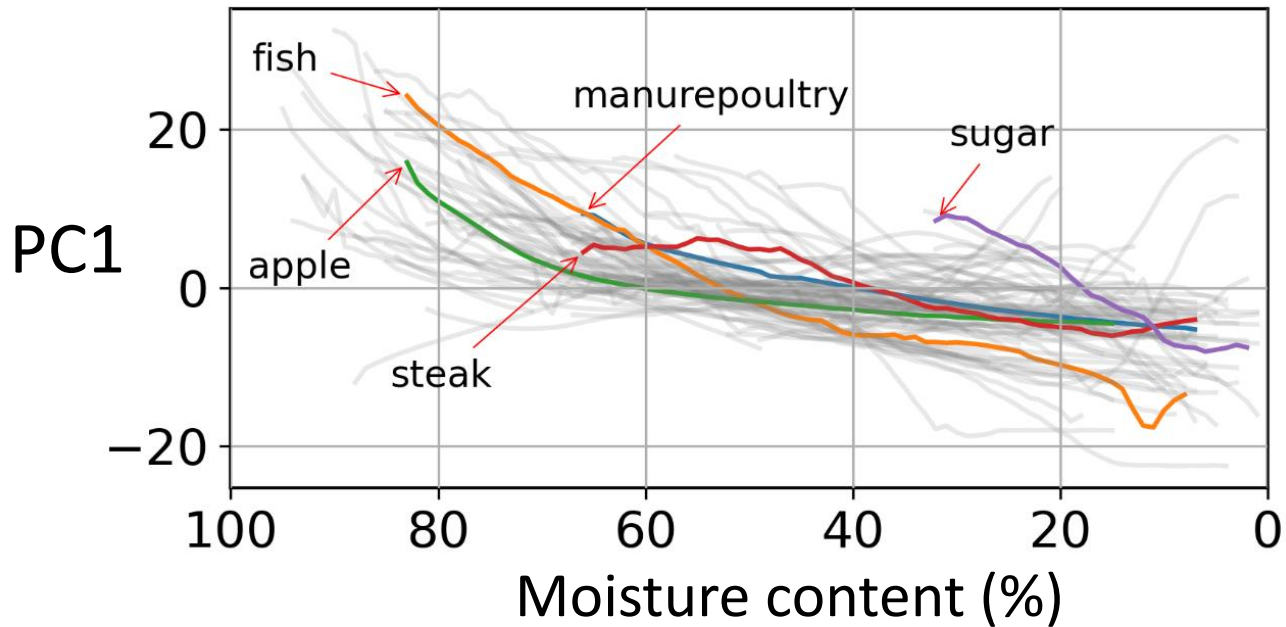

➤ **Explained variance (91.6%)**

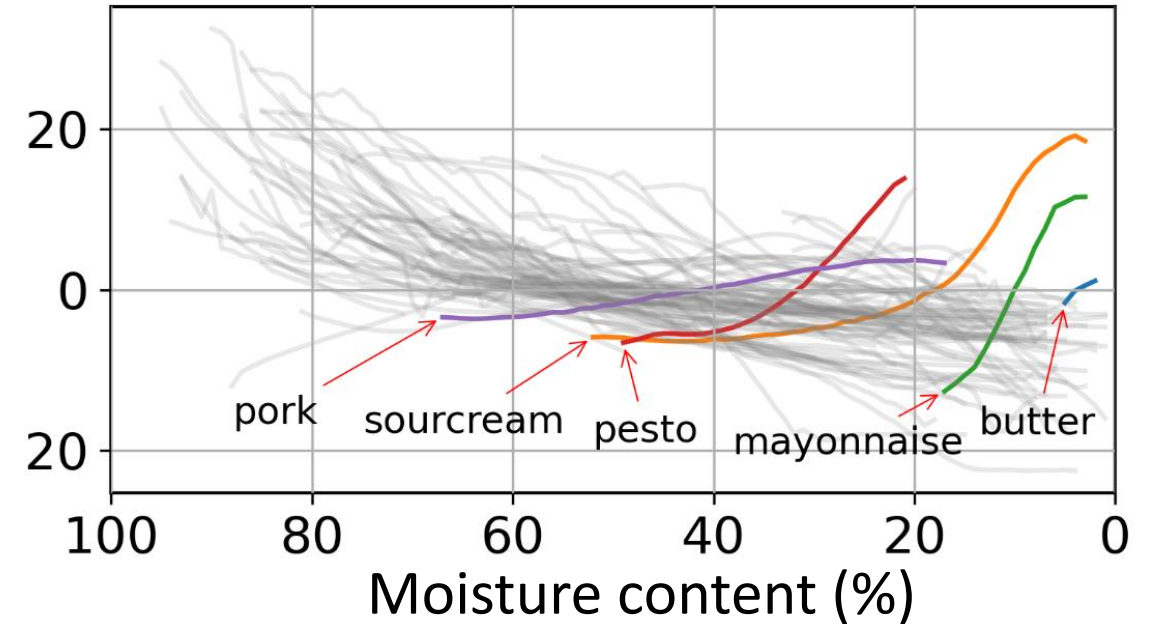

3.2 Non-linearity of water effects

Water affects physical properties (*ie.*, scattering)

Scores

Scores

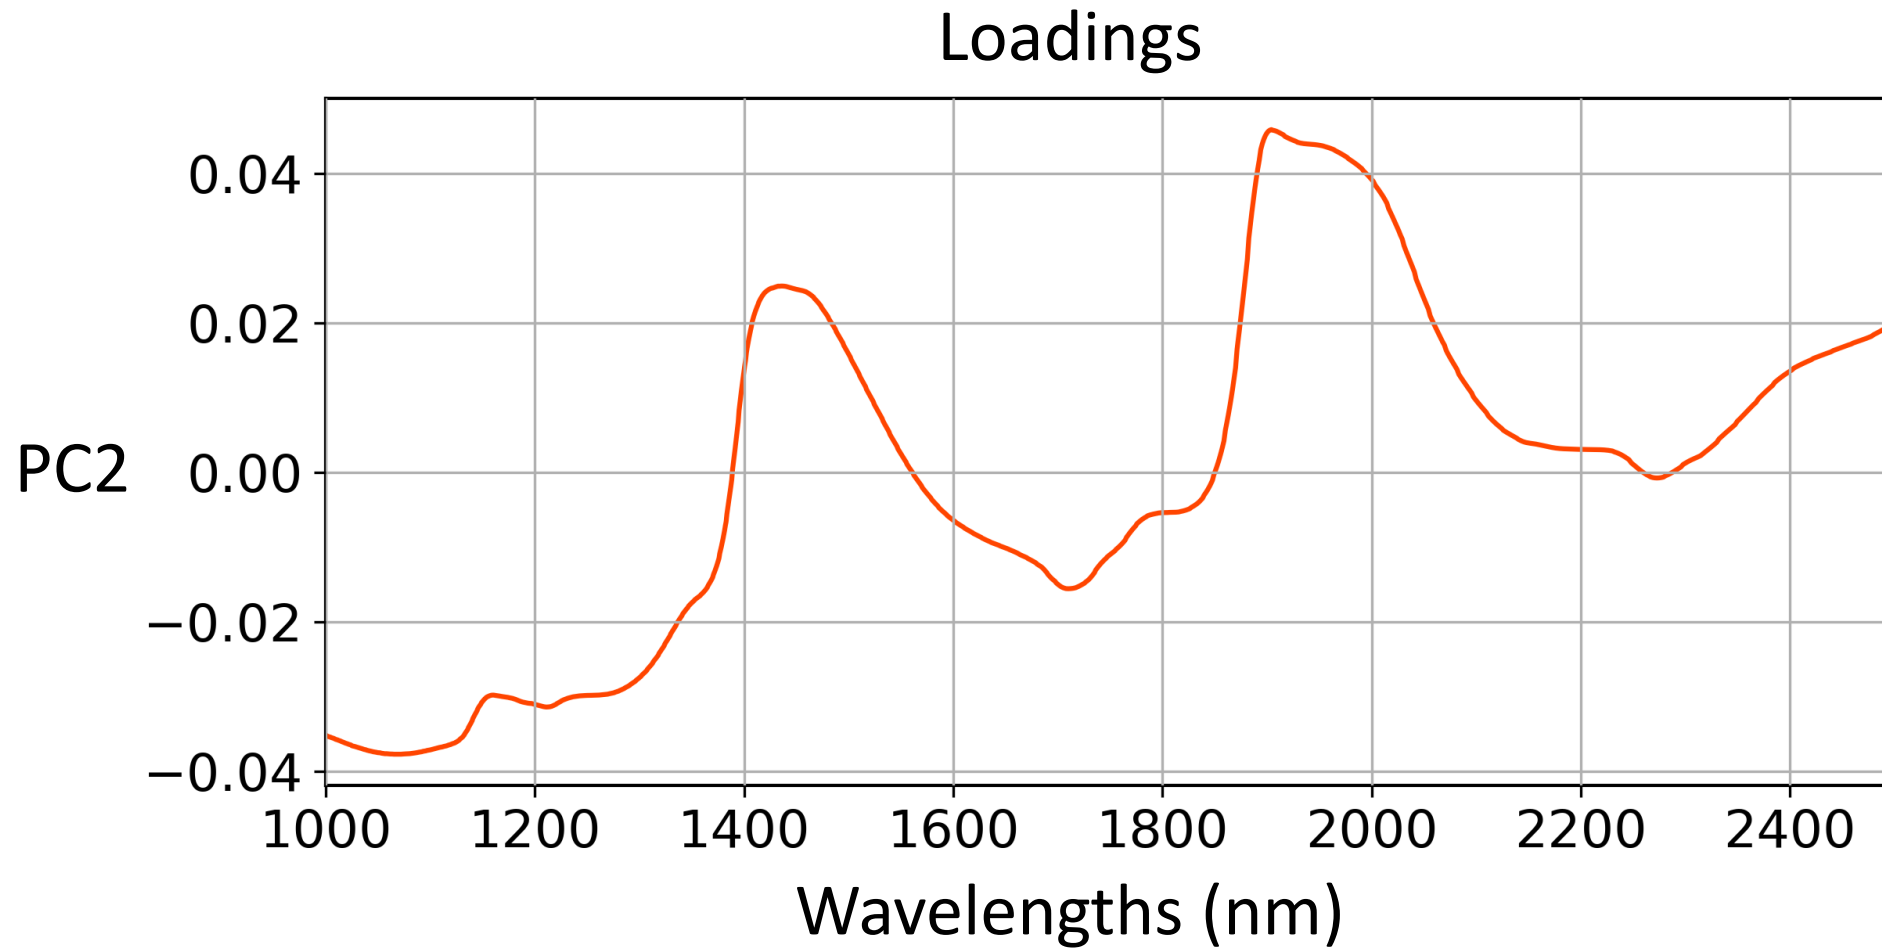

- Level of scattering evolves non-linearly with moisture content
- Dependence on biochemical composition: most substrates show decrease along drying, but high fat content samples show an increase

3.2

Non-linearity of water effects

Water affects chemical composition (*ie.*, absorption)

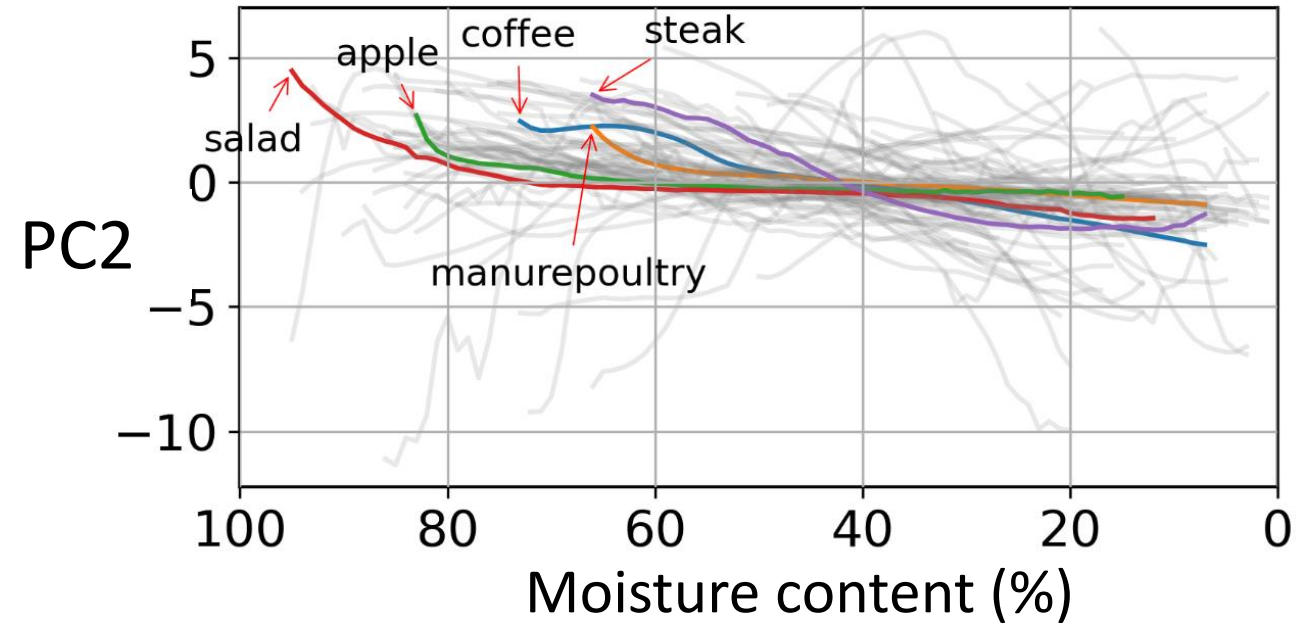

➤ **Explained variance (6.5%)**

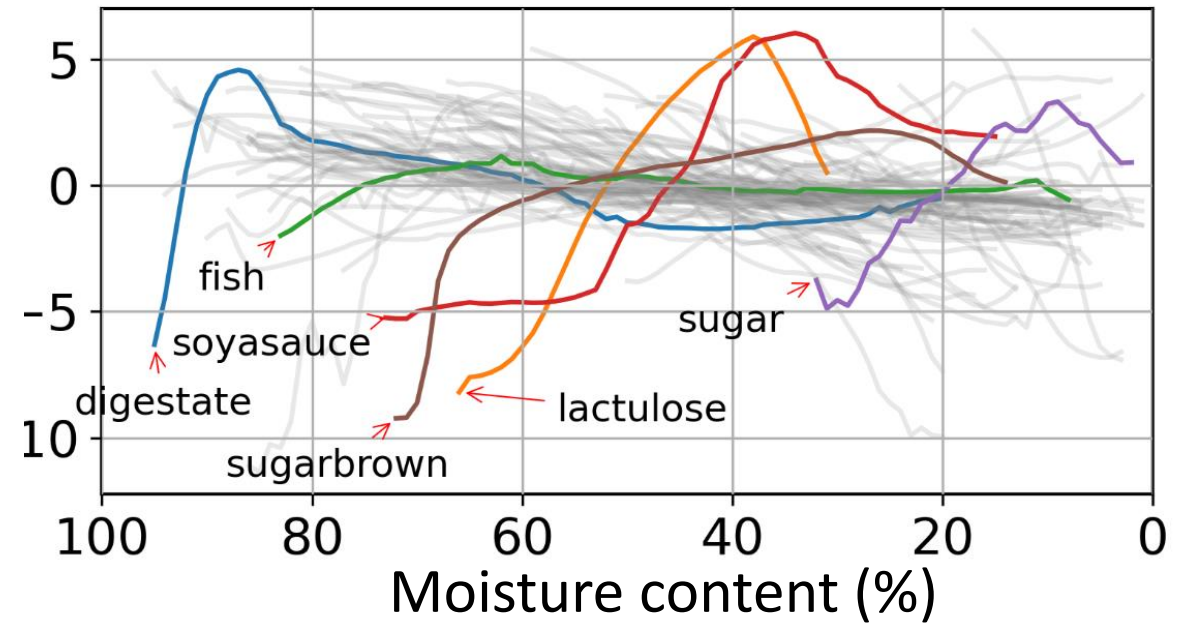

3.2 Non-linearity of water effects

Water affects chemical composition (*ie.*, absorption)

Scores

Scores

- OH absorption decrease along drying
- Saturation of water OH bands at high water content levels: forward scattering too high

3.2 Non-linearity of water effects

Conclusion

- **Water effects are complex:**
 - **Chemical effects** (absorption)
 - **Physical effects** (scattering)
- **Water effects depend on**
 - the **substrate type** (biochemical and physical properties)
 - the **moisture content level**
- **Physical effects account for the most variance: a need to better understand these effects**

3.3 Results - Water effects on light scattering

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on light scattering

3.4 – Local modeling

4 – Conclusions and perspectives

3.3 Water effects on light scattering

Objective, Materials & Methods

- **Objective:**
 - How does water modify light scattering?
 - Study physical effects independently from chemical effects

- **Proposed approach:**

Scattering media (particulate)

Limited chemical interactions
(no solubilization)

No absorption (dry mass)

Aluminum paper pellets
mixed with water

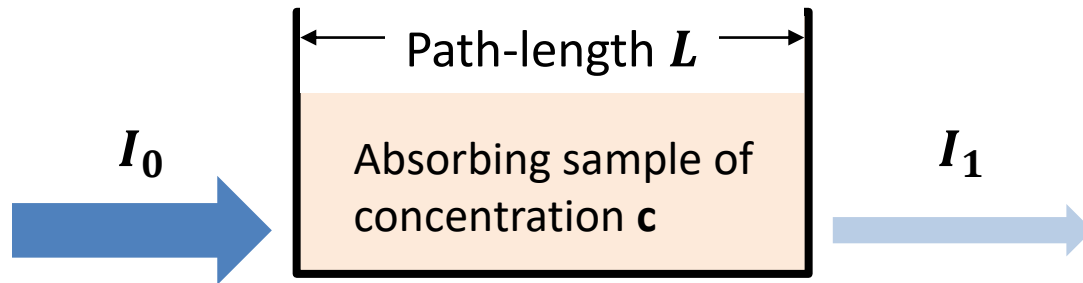

Criteria:

3.3 Water effects on light scattering

The Bouguer-Beer-Lambert (BBL) law framework

➤ Transmission measurements:

$$A = -\log(T) = -\log\left(\frac{I_1}{I_0}\right) = \epsilon_\lambda \cdot L \cdot c$$

A the **absorbance**, T the **transmittance**, ϵ_λ the **extinction coefficient**

➤ BBL law holds in very strict conditions¹⁻²:

- Homogeneous and fully transmitting medium
- Low concentrations
- Independence of absorbers
- Use of monochromatic light

[1] Swinehart et al., Jour. of Chemical Education, 1962.

[2] Mayerhöfer et al., ChemPhysChem, 2020.

3.3 Water effects on light scattering

What happens with scattering materials?

- In scattering media (powder, suspension), light scattering results in two phenomena¹

- 1) Path-length modifications
- 2) Photons loss

- One way of modeling²:

- 1) multiplicative effect (kL)
- 2) additive effect (f):

$$A = -\log(R) = -\log\left(\frac{I_1}{I_0}\right) = \epsilon_\lambda \cdot kL \cdot c + f$$

With k and f constants

[1] Gobrecht et al., Advances in Agronomy, 2014.

[2] Martens et al., Analytical Chemistry, 2003.

3.3 Water effects on light scattering

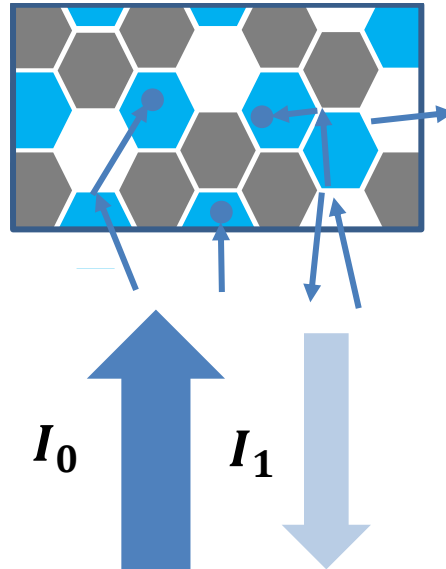

What about when moisture content varies?

- Forward scattering level is directly related to moisture content

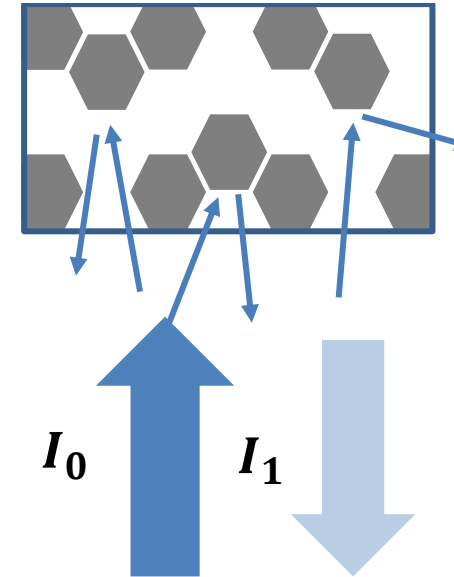

High moisture content

Medium moisture content

Low moisture content

- Water acts as a guide for photons
- Intuition was that it involved a geometrical relationship

3.3

Water effects on light scattering

New modeling of light path-length in the BBL law

Hypothesis: Light path-length is directly related to water content by a power law

$$L_{\lambda,c} = L_0 \cdot c^{a_\lambda}$$

With c water content,
 L_0 and a_λ constants

$$\Rightarrow A_{\lambda,c} = \varepsilon_\lambda \cdot L_0 \cdot c^{a_\lambda+1} + f_{\lambda,c}$$

3.3 Water effects on light scattering

New modeling of light path-length in the BBL

Hypothesis: Light path-length is directly related to water content by a power law

$$L_{\lambda,c} = L_0 \cdot c^{a_\lambda}$$

With c water content,
 L_0 and a_λ constants

$$\Rightarrow A_{\lambda,c} = \varepsilon_\lambda \cdot L_0 \cdot c^{a_\lambda+1} + f_{\lambda,c}$$

- To validate this, additive effects $f_{\lambda,c}$ were first removed using extended multiplicative scatter correction (EMSC)¹ to obtain $A_{\lambda,c} - f_{\lambda,c}$
- Then, a log-log least squares regression was run between $\log(A_{\lambda,c} - f_{\lambda,c})$ and $\log(c)$:

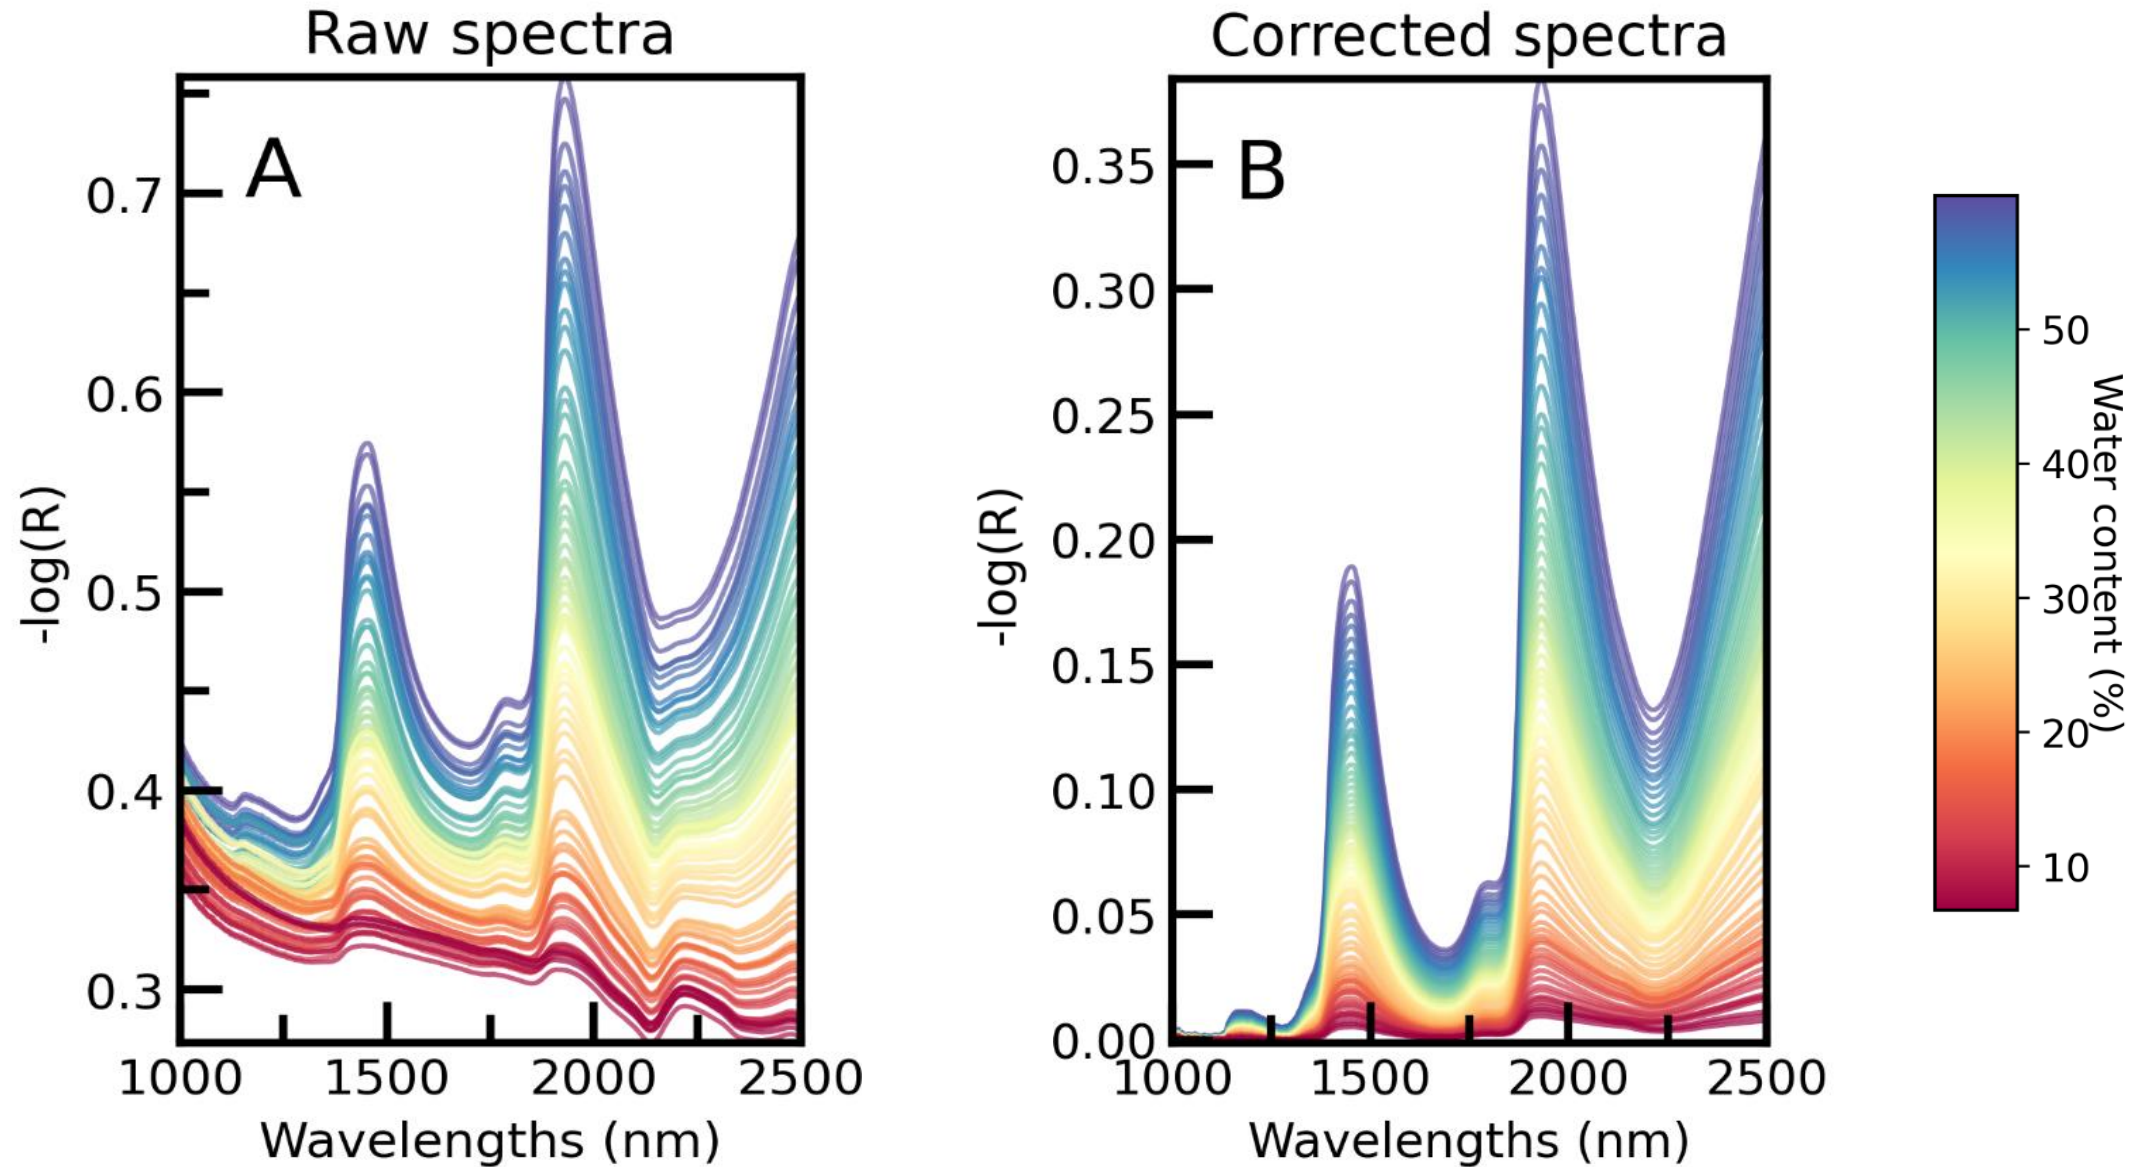

$$\log(A_{\lambda,c} - f_{\lambda,c}) = \log(\varepsilon_\lambda \cdot L_0) + (a_\lambda + 1) \cdot \log(c)$$

[1] Martens et al., Analytical Chemistry, 2003.

3.3

Water effects on light scattering

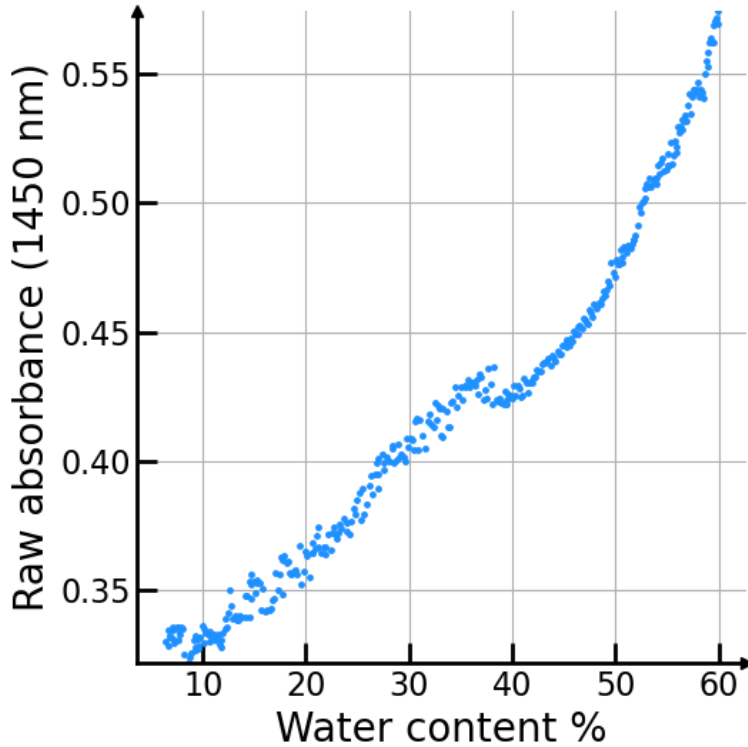

Correction of additive effects in spectra using EMSC

3.3 Water effects on light scattering

Results for one wavelength

Raw absorbance

Corrected absorbance

Log-log plot

➤ Analysis at a given wavelength (1450 nm) shows very good fit

$$\log(A_{\lambda,c} - f_{\lambda,c}) = \log(\epsilon_{\lambda} \cdot l_0) + (a_{\lambda} + 1) \cdot \log(c)$$

3.3 Water effects on light scattering

Results for all wavelengths

Good fit for all wavelengths (>1350nm)

Stable slope values (~1.5)

➤ This further validates the power law

3.3

Water effects on light scattering

Implications for quantitative calibrations

- Inadequacy of linear models
- Log transform could provide simpler models

3.3 Main conclusions of former studies

Conclusions

- Global **linear models were not reliable**
- Analysis of water effects
 - A **clear non-linearity** and a **dependence on both moisture content and substrate type**
 - **Scattering modifications can be modeled by a simple power law**

- Investigate the possibility of **building local models** (based on both **substrate type** and **moisture content**)

3.4 Results – Local modeling

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on scattering

3.4 – Local modeling

4 – Conclusions and perspectives

3.4

Local modeling

Local group of homogeneous samples

➤ 37(/89) selected substrates follow a power-law type relationship

3.4 Local modeling

Models built on this local group

➤ Local model still does not provide satisfactory results

➤ Power relationship not well modeled by PLS?

↳ non linear methods

➤ Biochemical footprint hidden by water?

↳ reduce moisture content range

3.4 Local modeling

Models built on this local group (reduced moisture content range)

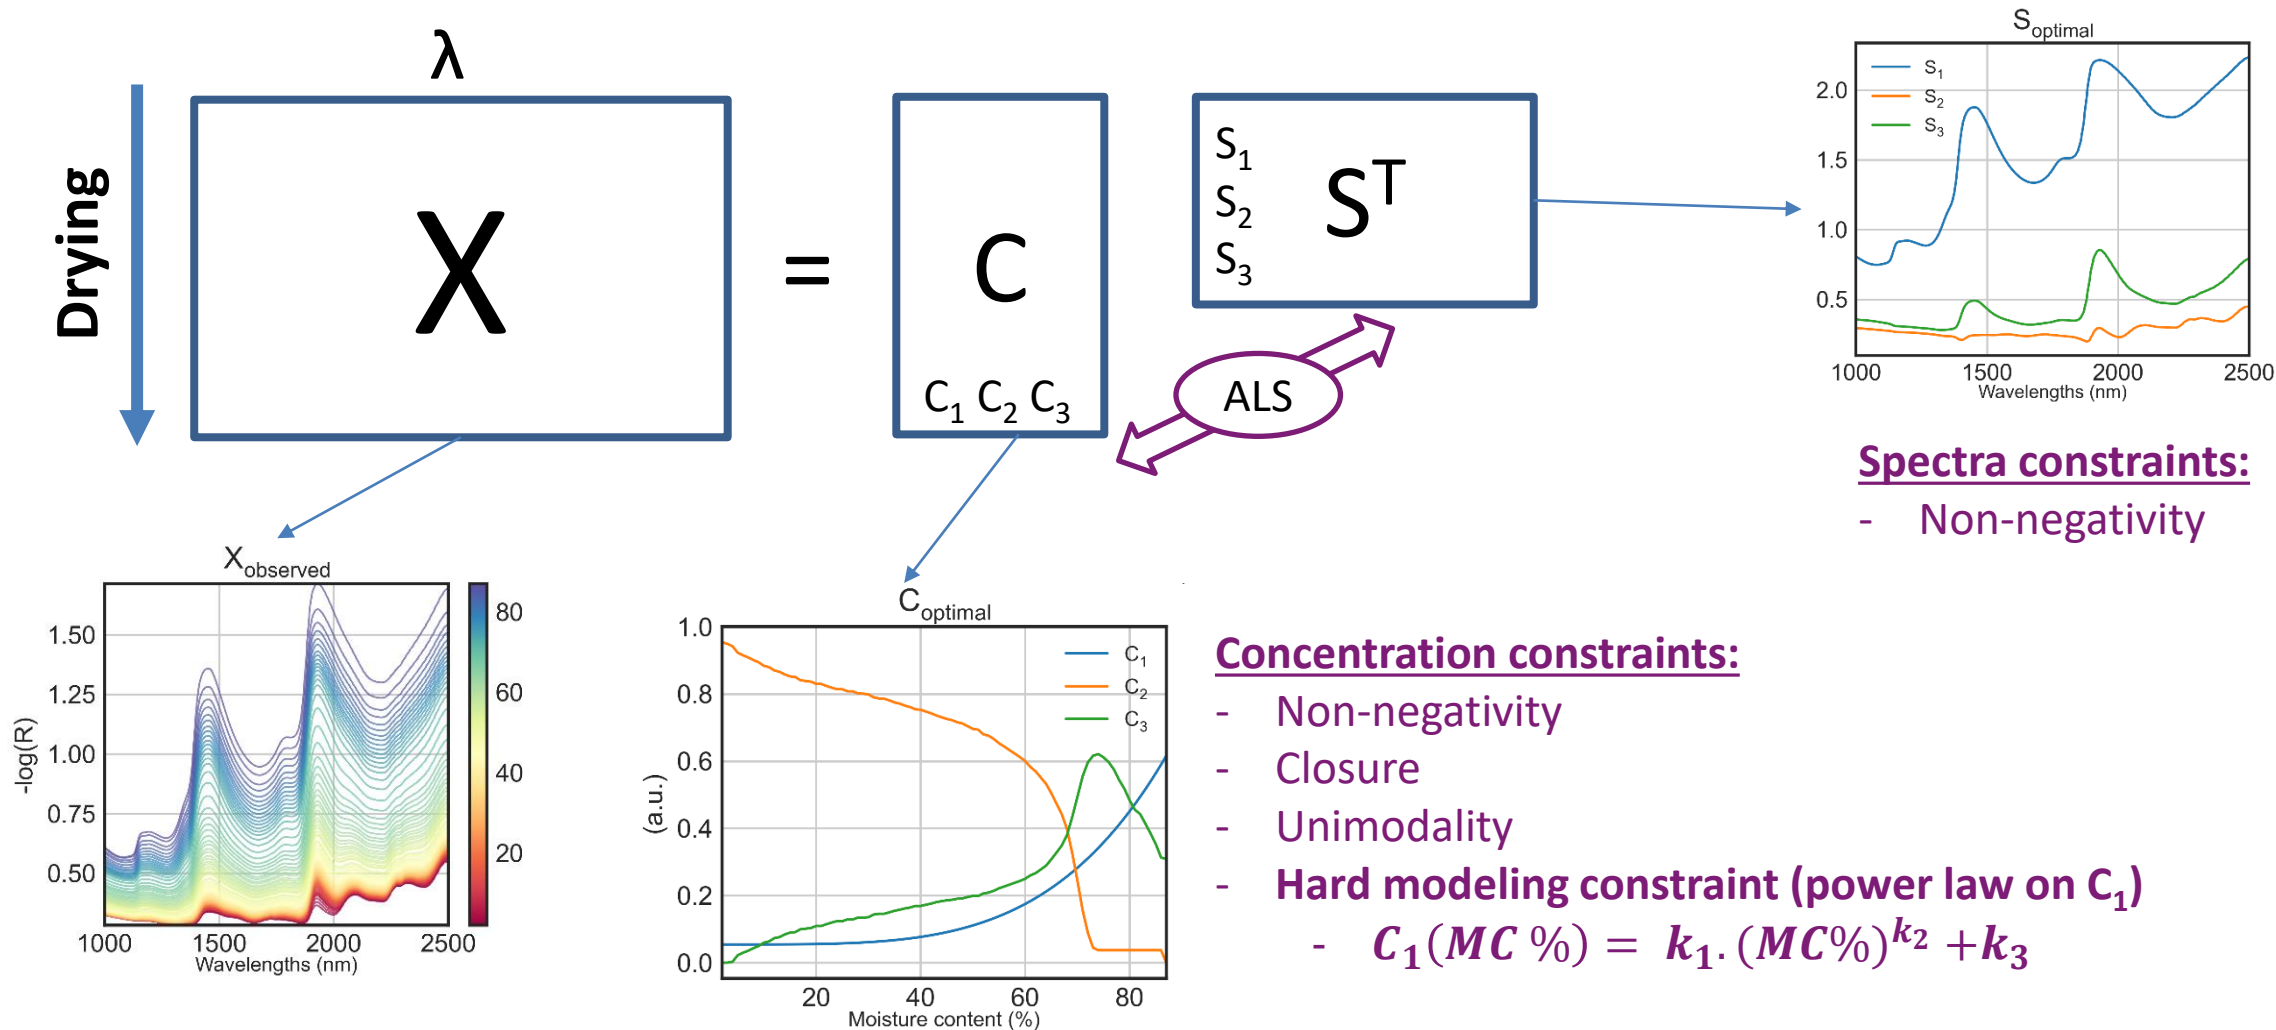

➤ More satisfactory models with reduced moisture content range

3.4 Local modeling

Potential of MCR-ALS to further refine local groups

➤ Adding the power law constraint to MCR-ALS framework¹

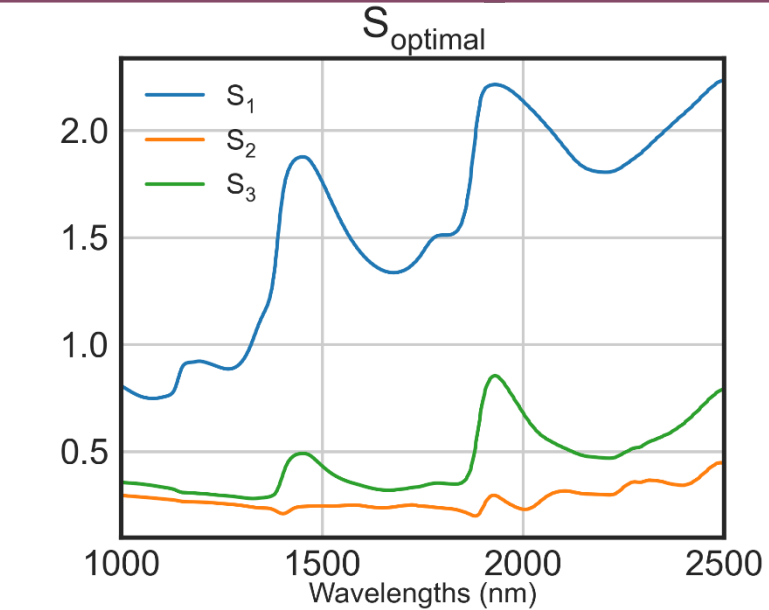

3.4

Local modeling

Potential of MCR-ALS to further refine local groups

Wheat chaff

Non-linearity

4. Conclusions and perspectives

1 – Introduction, context, scientific objectives

2 – Materials & Methods

3 – Results

3.1 – Global correction of models

3.2 – Non-linearity of water effects

3.3 – Water effects on scattering

3.4 – Local modeling

4 – Conclusions and perspectives

4.1 Conclusions and perspectives

Conclusions

- **Objective 1) To develop a better understanding of the moisture content effects on NIRS applied to a wide range of organic materials**
 - A new experimental set-up for analyzing water effects
 - Moisture content effects shown to be complex with both physical and chemical effects
 - Relating the path-length (power law) directly to moisture content could allow to better model the scattering modifications induced by water
- **Objective 2) To find new ways of building models that are robust to moisture content effects**
 - Global correction methods are insufficient due to non-linearity of effects
 - Local modeling holds promises

4.1 Conclusions and perspectives

Perspectives

- **Fundamental knowledge on water effects:**
 - Investigate the modified BBL law in more complex systems: how to deal with chemical interaction? How to remove additive effects?
- **Quantitative calibrations on wet samples:**
 - Develop the knowledge-based local approach with the help of MCR-ALS
 - Evaluate the potential of non-linear methods (local PLS, SVM, RT, RF, CNN)
 - Use NIRS measurements during drying as one predictor (N-way methods)
- **On-site and online applications:**
 - Sample preparation and measurements configurations are complementary strategies to reduce water effects
 - Pursue the evaluation of low-cost and handheld spectrometers applied to wet substrates

Thank you!
